Maheshwari, et al.: Analysis of salicylic acid by hydrotropic solubilization method

In the present investigation, the poorly water-soluble drug, salicylic acid has been solubilized using 0.5 M ibuprofen sodium and 2.0 M sodium salicylate solution as hydrotropic agents for the titrimetric analysis precluding the use of organic solvents. Both hydrotropes are economic and pollution-free. The mean percent estimation of salicylic acid estimated in bulk sample by Indian Pharmacopoeial method is 98.78%. The mean percent estimation by ibuprofen sodium method and sodium salicylate method are 99.25% and 98.82%, respectively. The results of analysis by the proposed method are very close to the results of analysis by the standard method. This confirms the accuracy of the proposed method. The proposed method was validated statistically by low values of statistical parameters viz. standard deviation, percent coefficient of variation and standard error. The proposed method is new, accurate, simple and economic.

Key words: Salicylic acid, hydrotropy, sodium salicylate, ibuprofen sodium, titrimetry

Hydrotropic solubilization technique is one of the methods used to enhance the aqueous solubility of insoluble or slightly soluble drugs. This technique involves the addition of large amount of additives in presence of which the aqueous solubility of the solute shows multifold enhancement1-17. Maheshwari analyzed various poorly water-soluble drugs, using hydrotropic solubilization phenomenon viz. frusemide1, tinidazole2, ketoprofen3, cefixime4 and ketoprofen5. Maheshwari et al. have developed various analytical techniques using hydrotropic solubilization phenomenon to analyze poorly water-soluble drugs, aceclofenac6, hydrochlorothiazide7, cephalaxin8 and piroxicam9. The Indian Pharmacopoeial method of titrimetric analysis of salicylic acid uses an organic solvent, ethanol for the solubilization of the drug.

Drawbacks of using an organic solvent include toxicity, high cost and environmental hazards. The primary objective of this study was to preclude the use of organic solvent and to employ hydrotropic solubilizing agents, ibuprofen sodium and sodium salicylate, which are economic.

All chemicals and solvents used were of analytical grade. Salicylic acid (S. D. Fine Chemicals Limited, Mumbai) was procured from market. Ibuprofen was obtained as gift sample from Shree Pharmaceuticals Ltd., Indore, India.

Solubility of salicylic acid was determined in distilled water and different concentrated solutions of hydrotropic agents at 27±1°. Enhancement of solubility of salicylic acid in 0.5 M ibuprofen sodium solution and 2.0 M sodium salicylate solution was more than 12-folds and 6-folds respectively (as compared to solubility in distilled water).
For the preparation of 0.5 M ibuprofen sodium solution, 10 g sodium hydroxide was dissolved in 200 ml distilled water. Ibuprofen (51.6 g) was added little at a time and stirred continuously to dissolve. After complete addition of ibuprofen, the pH was adjusted between 7.5-8.0 with additional sodium hydroxide solution to assure complete neutralization of ibuprofen.

For the analysis of salicylic acid by Indian Pharmacopoeial method (IPM)\(^8\), accurately weighed (0.3 g) salicylic acid bulk sample was solubilized in 50 ml of ethanol. After adding 20 ml distilled water, it was titrated with sodium hydroxide solution (0.1 M) using phenol red solution as indicator. Necessary blank determination was adjusted to get drug content (Table 1).

For the analysis of salicylic acid by ibuprofen sodium method (ISM), accurately weighed (0.3 g) salicylic acid bulk sample was solubilized in 40 ml of ibuprofen sodium solution (0.5 M) in a conical flask by shaking for about 5 min and titrated with sodium hydroxide solution (0.1 M) using phenol red solution as indicator. Necessary correction was done by conducting blank determination and amount of salicylic acid was calculated (Table 1).

For the analysis of salicylic acid by sodium salicylate method (SSM), accurately weighed (0.3 g) salicylic acid bulk sample was solubilized in 50 ml of sodium salicylate solution (2.0 M) in a conical flask by shaking for about 5 min and titrated with sodium hydroxide solution (0.1 M) using phenol red solution as indicator. Necessary corrections were done by conducting blank determinations and amount of salicylic acid was calculated (Table 1).

As evident from Table 1, the mean percent estimation of salicylic acid estimated in bulk sample by IPM is 98.78%. The mean percent estimation by ISM and SSM are 99.25% and 98.82%, respectively. The results of analysis by the proposed method are very close to the results of analysis by standard IPM. This confirms the accuracy of the proposed method.

The proposed method is validated statistically by low values of standard deviation, percent coefficient of variation and standard error (Table 1). Like salicylic acid, other poorly water-soluble drugs can also be subjected to analysis by using hydrotropic solubilization method. It is, thus, concluded that the proposed method is simple, cost-effective, accurate, safe and precise and can be successfully employed in the routine analysis of salicylic acid in bulk drug sample. There is a good scope for other poorly water-soluble drugs which may be tried to get solubilized by suitable hydrotropic agents to carry out their titrimetric analysis excluding the use of costlier and unsafe organic solvents.

**ACKNOWLEDGEMENTS**

The authors thank Shree Pharmaceuticals Ltd., Indore, India, for providing ibuprofen as a gift sample.

IPM refers to Indian Pharmacopoeial method, ISM refers to Ibuprofen sodium method and SSM refers to Sodium salicylate method; (n=4).

Estimation of Duloxetine Hydrochloride in Pharmaceutical Formulations by RP-HPLC Method

S. K. Patel college of Pharmaceutical Education and Research, Ganpat University, Kherava-382 711, India

Simple, specific, accurate and precise method, namely, reverse phase high performance liquid chromatography was developed for estimation of duloxetine HCl in pharmaceutical formulations. For the high performance liquid chromatography method, Phenomenox C-18, 5 µm column consisting of 250×4.6 mm i.d. in isocratic mode, with mobile phase containing 0.01M 5.5 pH phosphate buffer: acetonitrile (60:40 v/v) and final pH adjust to 5.5±0.02 with phosphoric acid was used. The flow rate was 1.2 ml/min and effluent was monitored at 231 nm. The retention time was 5.61 min. The method was validated in terms of linearity, accuracy and precision. The linearity curve was found to be linear over 0.25-4 µg/ml. The limit of detection and limit of quantification were found to be 0.10 and 0.25 µg/ml respectively. The proposed method was successfully used to determine the drug content of marketed formulations.

Key words: Duloxetine HCl, isocratic mode, RP-HPLC, SSNRI

Duloxetine HCl (DLX) is chemically, 2(+)-(S)-N-methyl-(gamma)-(1-naphthyloxy)-2 thiophenepropylamine hydrochloride. Duloxetine hydrochloride is a newer selective serotonin and norepinephrine reuptake inhibitor (SSNRI) used for major depressive disorders. Duloxetine is not official in any pharmacopoeia. A few methods in literature were reported for the determination of DLX and its key intermediate, desmethyl duloxetine in human serum by HPLC method. Literature reported the characterization of phenolic impurities in duloxetine HCl samples by MS, NMR, X-ray-analysis and impurities formed by interaction of duloxetine HCl with various enteric polymers. Simple UV Spectrophotometric method for estimation of duloxetine in formulation is reported but calibration range is from 5-50 µg/ml that shows the method is less sensitive. The present investigation describes a simple, rapid and reproducible RP-HPLC method with a calibration range of 0.25-4 µg/ml for duloxetine HCl in capsule dosage form that is more appropriate for routine analysis.
