Rani, et al.: Antimicrobials from Pteridophytes

Plants are an important source of neutraceuticals that have proved to be effective against important microbial infections of humans. Lower plants are gaining importance in this regard. The present study is aimed at investigating the antimicrobial properties of three selected ferns, *Psilotum nudum*, *Nephrolepis biserrata* and *Nephrolepis cordifolia*. The aerial parts of the selected ferns, *P. nudum*, *N. biserrata* and *N. cordifolia*, were fractionated in different solvents. These fractions were concentrated to obtain a powder and were tested against nine bacterial and three fungal strains according to disc diffusion method. The water and ethanol fractions were active against most of the tested bacterial and fungal strains, some of these were more effective than the controls tested. Present study suggests that the pteridophytes, *P. nudum*, *N. biserrata* and *N. cordifolia* could be good source of antimicrobials. These natural compounds might be more effective as the microbes may have lesser chance of developing resistant mutants.

Key words: Antibacterial, antifungal, dermatophytes, disc diffusion assay, *Nephrolepis biserrata*, *Nephrolepis cordifolia*, *Psilotum nudum*, pathogenic bacteria

Use of antibiotics is often associated with adverse effects such as hypersensitivity, depletion of beneficial gut and mucosal microorganisms, immune-suppression and allergic reactions in the user. Besides, the indiscriminate use of antimicrobial drugs has created immense clinical problems in the treatment of infectious diseases¹, as the microorganisms develop resistance to often used antibiotics. This necessitates development of alternative antimicrobial drugs, for the treatment of infectious diseases, from the medicinal herbs which are a rich source of novel antibacterial...
and antifungal chemotherapeutics\(^2\). Angiosperms are an immense source of therapeutics. However, lower plants are attracting more attention in recent times for the search of new and effective molecules. The medicinal value of the pteridophytes has been known for several years. Antimicrobial properties of ferns are remarkable as compared to the higher plants may be because of the presence of a large number of defensive biochemical compounds\(^3,4\).

The present study has been undertaken to assess the antimicrobial properties and therapeutic value of three pteridophytes *P. nudum*, *N. biserrata* and *N. cordifolia*. This is the first report of the antibacterial and antifungal properties of the non-aqueous frond extracts of these three pteridophytes. *P. nudum* is an epiphyte that grows as a terrestrial plant in rocky crevices or in sandy soils and being a spore-producing vascular plant is considered to be a fern ally\(^4\). Ethnomedicinal uses of *P. nudum* are as general pain reliever especially dental pains and for easing bowls\(^5\). This pteridophyte is reported to contain an alkaloid psilotin, an insect feeding deterrent and growth reducer\(^6\) and 3’-hydroxypsilotin, a glycoside\(^7\). *N. biserrata* and *N. cordifolia* belong to the family Davalliaceae and have been reported to be of immense ethnobotanical importance. *N. biserrata* is widely distributed and having escaped cultivation has become naturalized in many countries. Its ethnomedicinal importance in boils, abscesses and blisters is well known\(^8\). Incidentally, boils\(^9\) and abscess\(^9\) are due to bacterial infections and blisters are caused by fungal infection\(^10\). Thus, *N. biserrata* can be a potential fern to fight against pathogenic microbes. *N. cordifolia* is a pantropical species growing from tropical to temperate areas\(^11\) and ethnomedically used in general disorders of renal and liver systems, skin diseases and as a contraceptive\(^5\). Aqueous extracts of *N. cordifolia* have been earlier reported to have antimicrobial activity\(^12\).

The extracts were prepared from the fronds of *P. nudum*, *N. biserrata* and *N. cordifolia* growing in the fern house of National Botanical Research Institute, Lucknow. The fronds were dried in shade, powdered and extracted with 50% ethanol in a percolator. The extracts were concentrated in a rotavapour (Eyela, Japan) at 45°. The concentrate was lyophilized to a dry yellowish to brownish powder and weighed. The lyophilized powder was then fractionated three times separately in hexane, chloroform, ethanol and water in that order. Each of these fractions was used as a test extract\(^3,13-16\).

Preliminary phytochemical screening of the extracts obtained from the three plants was performed for, flavonoids using Shinoda’s test\(^17\), tannins through Ferric chloride test\(^18\), alkaloids using Dragendorff’s test\(^19\), reducing sugars with Fehling’s test\(^20\), triterpenoids with Liebermann-Burchard’s test\(^21\) and steroids as described by Hardman and Sofowora\(^22\). The antibacterial effect of the fern extracts was studied on nine bacterial strains, namely, *Proteus mirabilis* (MTCC-1429), *Pseudomonas aeruginosa* (MTCC-424), *Salmonella typhimurium* (MTCC-98), *Bacillus subtilis* (MTCC-121), *Streptococcus faecalis* (MTCC 1927), *Staphylococcus aureus* (MTCC-96), *Klebsiella pneumoniae* (MTCC-109), *Bacillus cereus* (MTCC-430), *Shigella flexneri* (MTCC 1456) and *Escherichia coli* (MTCC-443), chosen because of their pathogenicity. The pure cultures of these bacterial strains were obtained from the Institute of Microbial Technology (IMTECH), Chandigarh, India. Antifungal activity of the extracts was tested on three fungal species, namely, *Microsporum gypseum* (ATCC-24102), *Trichophyton mentagrophytes* (ATCC-9533) and *Trichophyton rubrum* (ATCC-28188) that are important dermatophytes. The fungal strains were procured from Himedia, India.

The bacteria were maintained and tested on Mueller Hinton Agar/Broth (MHA/MHB, Oxoid). The fungi were maintained and tested on Saubouraud Dextrose Agar/broth (SDA/SDB, Oxoid). Prior to pouring into petriplates all media were sterilized at 121° and 15 lbs for 20 min.

Agar disc diffusion method\(^23\) was used to evaluate the antimicrobial activity. A final inoculum of 100 µl suspension containing 10⁸ CFU/ml of each bacterium and fungus was used. The bacterium was spread on Mueller Hinton Agar (MHA) medium and each fungus was spread on Saubouraud Dextrose Agar. The disc (6 mm diameter) was impregnated with 10 µl of 50 mg/ml extracts and placed on the seeded agar. Gentamycin (30 µg/disc) and erythromycin (30 µg/disc) were used as positive controls for bacterial pathogens and ketoconazole (30 µg/disc) and amphotericin-B (30 µg/disc) were used as positive controls for the fungal pathogens. The test plates were incubated at 37° for 24 h for bacterial pathogens and 27° for 72 h for fungal pathogens or
for a period required for a visible growth\(^{[24]}\). Each set of experiment was performed in triplicates\(^{[12]}\).

The phytochemical tests indicated the presence of all the metabolites such as flavonoids, tannins, alkaloids, reducing sugars, triterpenoids and steroids in the three pteridophytes, \(P.\) \(nudum\), \(N.\) \(biserrata\) and \(N.\) \(cordifolia\). The yield on fractionation of the crude extract varied depending on the solvent used. The water fraction gave the maximum yield and it was as follows: \(P.\) \(nudum\) - 662 \(\mu\)g/ml, \(N.\) \(biserrata\) - 679 \(\mu\)g/ml and \(N.\) \(cordifolia\) - 788 \(\mu\)g/ml. In the chloroform fraction the yield was maximum for \(P.\) \(nudum\) (59 \(\mu\)g/ml) and quiet less for \(N.\) \(biserrata\) (9 \(\mu\)g/ml) and \(N.\) \(cordifolia\) (3 \(\mu\)g/ml). The yield of hexane fraction was maximum for \(P.\) \(nudum\) (62 \(\mu\)g/ml) followed by \(N.\) \(biserrata\) (33 \(\mu\)g/ml) while \(N.\) \(cordifolia\) yielded only 6 \(\mu\)g/ml. The ethanol fraction yielded more or less the same amount for \(P.\) \(nudum\) (34 \(\mu\)g/ml) and \(N.\) \(cordifolia\) (37 \(\mu\)g/ml) and was only marginally less for \(N.\) \(biserrata\) (24 \(\mu\)g/ml).

The results of the effect of various extracts and controls are presented in Table 1 for the bacterial strains and in Table 2 for the fungal strains. Water extract of all the three species was the most effective in inhibiting growth of all the bacterial strains (Table 1). The water extracts of \(P.\) \(nudum\) was least effective in inhibiting the growth of \(P.\) \(aerugenosa\) and most effective against \(Salmonella\) \(typhimurium\), that of \(N.\) \(biserrata\) was less inhibitory to the growth of \(Enterobacter\) \(aerogenes\) and most inhibitory against \(Escherichia\) \(coli\) and \(N.\) \(cordifolia\) extract was least inhibitory on the growth of \(Proteus\) \(mirabilis\) and \(Streptococcus\) \(feacalis\) and most effective against \(Salmonella\) \(typhimurium\) and \(Bacillus\) \(cereus\). None of the water extracts were as effective as the gentamycin or erythromycin controls in inhibiting the growth of the bacteria (Table 1).

The hexane extracts of the three plants did not have antimicrobial activity against any of the nine bacterial strains tested. The chloroform extract of the two species of \(Nephrolepis\) and ethanol extract of \(N.\) \(biserrata\) also did not display any antibacterial activity. The ethanol extract of \(N.\) \(cordifolia\) was only marginally effective against \(Proteus\) \(mirabilis\), \(Enterobacter\) \(aerogenes\), \(E.\) \(coli\) and \(Klebsiella\) \(pneumonia\). The ethanol extract of \(P.\) \(nudum\) was marginally effective in inhibiting the growth of all

the bacterial strains except *B. cereus* which was not inhibited at all, while the chloroform extract was not effective against *Bacillus cereus* and *Streptococcus faecalis*.

The water extracts of all the three pteridophytes exhibited some degree of inhibition against the fungi tested. None of the hexane extracts of any of the plants had inhibitory effect. Ethanol extract of the two species of *Nephrolepis* did not have any inhibitory effect on the fungi tested, while chloroform extract of only *N. biserrata* exhibited inhibitory effect against only one fungal strain, *Trichophyton rubrum*. *P. nudum* was the only pteridophyte amongst the three studied whose chloroform, ethanol and water extracts exhibited antifungal properties against all the fungi tested. Of these the ethanol extract was the most effective and its inhibition of the two species of *Trichophyton* was marked. The chloroform extract though less effective than the ethanol extract was marginally better than the water extract. However, the water extract of *P. nudum* was marginally better than that of the two species of *Nephrolepis*. None of the extracts could equal the inhibition by ketoconazole or amphotericin-B controls (Table 2).

The three pteridophytes, *P. nudum*, *N. biserrata* and *N. cordifolia* possess both antibacterial and antifungal properties. Most of the extracts in the present study were effective against both gram positive and gram negative bacteria unlike *Lantana* extract which was more effective against gram positive bacteria. The water extract of the three pteridophytes had the most inhibitory effect against the bacterial and fungal strains tested. The findings of the present study validate the earlier investigation that aqueous extract of *Nephrolepis* did not show any appreciable antifungal properties. All the three extracts of *P. nudum* were effective against the fungal pathogens tested. In an earlier exhaustive study covering 114 species of pteridophytes 73 displayed antimicrobial properties, but *Psilotum nudum* and *Nephrolepis biserrata* were not part of it and only the water extract of *N. cordifolia* was shown to exhibit antimicrobial property. *Adiantum* species has been reported to contain significant antimicrobial properties. The present study confirms the earlier findings that pteridophytes and other lower plants should be further screened for generating biologically active compounds. *P. nudum*, a primitive pteridophyte, possesses better antibacterial and antifungal properties than the ferns, *N. biserrata* and *N. cordifolia*. The above findings advocate further investigations of the extracts from various parts of *P. nudum* and the two species of *Nephrolepis* to identify the active constituents.

ACKNOWLEDGEMENTS

One of the authors Dolly Rani would like to thank the Director, National Botanical Research Institute, Lucknow, for providing facility to carry out the present work.

In Vitro Evaluation of Domperidone Mouth Dissolving Tablets

S. PATRA*, R. SAHOO, R. K. PANDA, K. HIMASANKAR AND B. B. BARIK

University Department of Pharmaceutical Sciences, Utkal University, Vani Vihar, Bhubaneswar - 751 004, India

Patra, et al.: Domperidone Mouth Dissolving Tablets

In the present research work mouth dissolving tablets of domperidone were developed with superdisintegrants like crospovidone, croscarmellose sodium and sodium starch glycollate in various concentrations like 3%, 4% and 6% w/w by direct compression method. All formulations were evaluated for physical characteristics of compressed tablets such as weight variation, hardness, friability, content uniformity, *in vitro* disintegration time, wetting time and *in vitro* drug release. Among all, the formulation F3 (containing 6% w/w concentration of crospovidone) was considered to be the best formulation, having disintegration time of 9 s, wetting time of 15 s and *in vitro* drug release of 99.22% in 15 min.

Key words: Crospovidone, domperidone, mouth dissolving tablets, superdisintegrants, croscarmellose sodium, sodium starch glycollate

Dysphagia is a common problem encountered in all age groups in concern to solid dosage forms, which results in high incidence of non-compliance and ineffective therapy [1]. Recent advances in novel drug delivery systems (NDDS) aim to enhance safety and efficacy of drug molecule by formulating a convenient dosage form for administration and to achieve better patient compliance. To overcome this problem, scientists have developed innovative drug delivery systems known as melt-in-mouth or mouth dissolve (MD) tablets [2]. Advantages of this drug delivery system include administration without water, accuracy of dosage, easy portability, alternative to liquid dosage forms, ideal for pediatric and geriatric patients and rapid onset of action [3-5].

The basic approach used in the development of the fast-dissolving tablet is the use of superdisintegrants like crospovidone, croscarmellose sodium (Ac-Di-Sol), and sodium starch glycollate (Primogel). In the present study these superdisintegrants were evaluated at different concentrations to develop MD tablets and selected the best formulation. Another approach that can be used in developing MD tablets is maximizing pore structure of the tablets. Freeze-drying [6,7] and vacuum-drying [8-10] techniques have been tried by researchers to maximize the pore structure of tablet matrix.

Domperidone is widely used antiemetic drug acting by an inhibition of the dopaminergic receptors. Domperidone does not cross blood brain barrier. Domperidone is also effective in gastroparesis, paediatric gastroesophageal reflux (infant vomiting). Domperidone after oral dosing undergoes extensive gastric and hepatic first pass metabolism resulting in low bioavailability (15%) which therefore, may not...
