Zhang *et al.*: Radical Gastrectomy in the Treatment of Gastric Cancer

To investigate the safety and efficacy of different radical gastric cancer treatments in the management of gastric cancer. The literature published in the last 5 y was searched for recent outcomes of different radical gastric cancer procedures used in the treatment of gastric cancer. 14 papers were finally included according to the established screening criteria. The trial design, study population characteristics and findings of the included studies were abstracted using randomized independent trials and statistically analyzed using RevMan 5.0 software. The results of the meta-analysis showed that laparoscopic early distal gastric cancer surgery compared with conventional open surgery: The operative time was 49.85 min longer ($p < 0.05$), but intraoperative bleeding was 145.50 ml less ($p < 0.05$), the number of postoperative analgesic requests was 1.22 less ($p = 0.01$) and the number of days to the first postoperative vent was 0.57 d shorter ($p < 0.05$), the number of days to the first postoperative meal was shortened by 0.88 d ($p < 0.05$); the number of postoperative hospital days was shortened by 4.76 d ($p < 0.05$) and the incidence of postoperative complications was low, both differences were statistically significant ($p < 0.05$). The recent efficacy of laparoscopy-assisted distal gastrectomy in treating gastric cancer was significantly better than that of conventional open distal gastrectomy.

Key words: Gastric cancer, gastrectomy, laparoscopy, meta-analysis

With the rapid development of endoscopy technology and the general acceptance of endoscopy among high risk groups, more and more patients with early gastric cancer have received timely diagnosis and treatment. Due to the high 5 y survival rate of patients with early gastric cancer, minimally invasive and safe surgery to improve the quality of life of patients after surgery is of great significance. In 1991, Kitano *et al.* first carried out Laparoscopy-Assisted Distal Gastrectomy (LADG) for the treatment of early gastric cancer^[1]. After nearly 20 y of development, the minimally invasive advantages of LADG compared to Conventional Open Distal Gastrectomy (CODG) in the treatment of early distal gastrectomy have become more obvious. In this study, we studied the literature published in recent years about the recent efficacy of LADG vs. CODG and performed a meta-analysis to further prove the safety and feasibility of laparoscopic early distal gastric cancer surgery.

MATERIALS AND METHODS

Research type and object:

In recent years, we searched complete laparoscopic

radical gastric cancer surgery and laparoscopic-assisted radical gastric cancer surgery (Randomized Controlled Trial (RCT), retrospective observational research, Retrospective Non-Randomized Trial (RNT)).

Literature inclusion criteria:

Documents that meet the following requirements will be the research objects of this article: The published English documents of CODG and LADG surgical comparative studies, RCT and RNT can be selected; The research data provides a clear number of patients, case selection criteria, description of the grouping method and contains at least 2 relevant analysis data; The selected literature must clearly record that the operation method is fully laparoscopic and laparoscopically assisted; For the original data of relevant literature, continuous variables should provide mean and standard deviation; binary variables should provide combined Odds Ratio (OR) value and 95 % Confidence Interval (CI) or can be converted into OR value and its 95 % CI regression coefficient and its standard error; For the literature of the same unit, select the literature of higher quality or

*Address for correspondence

E-mail: ym04161564@163.com

the most recently published literature for statistics; The original text must be published in English and other languages will not be included.

Literature exclusion criteria:

The following documents were not included in this study: No CODG or LADG in the surgical method; Cases of hand-assisted laparoscopic radical gastric cancer surgery included in laparoscopic surgery; Cases of other surgical diseases included in the selected cases; The selected cases contain palliative gastric cancer surgery cases; Historical control and other non-contemporaneous controlled research literature; This study does not require the patient's disease stage, surgical resection range, and lymph node dissection range, but excludes two, the group has obvious grouping tendency or significantly different results in the disease stage or the scan range of the lymph node.

Evaluation of the quality of literature:

This article uses the "*" symbol method to evaluate the quality of the selected documents^[2]. There are a total of 11 evaluation indicators. The data of each evaluation indicator of all selected documents are extracted. If one of the evaluation indicators is met, it will be 1*. If all 11 evaluation indicators of the selected documents are met, 11* will be awarded; if 1 document is* the number reaches the total number of * > 50 %, the quality is considered to be better.

Data extraction:

Three experts with rich professional knowledge background use a unified data table to extract data and vote by show of hands in case of dispute. The content of the extracted data includes: Publication time, first author, disease period, number of patients, surgical operation time, intraoperative blood loss, range of lymph node dissection, number of lymph node dissection, distance between proximal and distal resection edges, intestinal tract. The time of the first exhaust after the operation,

the time of the first liquid intake after the operation and the length of the patient's hospital stay.

Statistical analysis:

In this meta-analysis, the Review Manager 5.2 statistical software provided by the Cochrane Collaboration was used for analysis and the data were merged and tested for heterogeneity. If the data has no obvious heterogeneity ($I^2 \leq 50\%$), the fixed effects model can be used. If the data is heterogeneous ($I^2 > 50\%$), the random effects model must be used to calculate the combined effect size. For binary variables, we use Relative Risk (RR), while for continuous variables with the same unit of measurement, we use the Weighted Mean Difference (WMD) and for continuous variables with different units of measurement, we use the Standardized Mean Difference (SMD), each effect size is represented by a 95 % CI.

Evaluation of the quality of selected documents:

A total of 14 studies comparing the short-term efficacy of LADG and CODG were selected^[3-16]. Since there are only 4 relevant RCTs and they are all small sample studies^[3-6]. Considering that the sample size is also an important factor affecting the results, this study also included 10 RNTs to make up for the simple. The disadvantage of insufficient sample size of RCT^[7-16]. The selected documents are all > 6*. As shown in Table 1.

Descriptive analysis of the characteristics of all included studies:

There were 27 cases with the smallest sample size^[12] and 211 cases with the largest sample size^[10]. The total sample size of the whole study was 1394 cases, 755 cases were in the LADG group and 639 cases were in the CODG group. Wing checked that all the selected studies were in full compliance with the selection criteria. The characteristics of all studies are shown in Table 2 and fig. 1.

Fig. 1: Meta-analysis funnel chart

Meta-analysis of operation time comparison:

A total of 14 studies compared the operation time of LADG and CODG were included in this meta-analysis sample size of 1394 cases. Among them, 4 RCTs and 5 RNTs considered that the operation time of LADG was longer than that of CODG was statistically significant; the remaining 5 RNTs considered that the operation time of LADG and CODG was similar and the difference was not statistically significant. The meta-analysis results showed that the operation time of LADG was 49.85 min longer than that of CODG ($p < 0.05$) and the difference was statistically significant, as shown in fig. 2.

Meta-analysis of intraoperative blood loss comparison:

A total of 13 studies comparing the intraoperative blood loss of LADG and CODG were included in this meta-analysis, with a sample size of 1247 cases. Among them, 2 RCTs and 8 RNTs believed that LADG had less intraoperative blood loss than CODG and the difference was statistically significant; the remaining 3 RNTs believed that LADG and CODG had similar intraoperative blood loss and the difference was not statistically significant; the results of meta-analysis showed, intraoperative blood loss of LADG was 97.50 ml less than CODG ($p < 0.05$) and the difference was statistically significant, as shown in fig. 3.

Meta-analysis of the number of times required for postoperative analgesics:

A total of 7 studies comparing LADG and CODG's required number of postoperative analgesics were included in this meta-analysis, with a sample size of 605 cases. Among them, 2 RNT considered that the number of requests for analgesics after LADG was less than CODG and the difference was statistically significant; the remaining 3 RCTs and 2 RNT considered that the number of requests for analgesics after LADG and CODG was similar and the difference was not statistically significant. Meta-analysis results showed that the number of analgesics required after LADG was 1.22 times lower than that of CODG ($p = 0.01$) and the difference was statistically significant, as shown in fig. 4.

Meta-analysis of the number of days after the first exhaust:

A total of 10 studies comparing LADG and CODG postoperative days of the first exhaust were included in this meta-analysis, with a sample size of 829 cases. Among them, 3 RCTs and 4 RNT considered that the first exhaust days after LADG were shorter than CODG and the difference was statistically significant; the remaining 1 RCT and 2 RNT considered that the first exhaust days after LADG and CODG were similar. The difference was not statistically significant; the results of meta-analysis

showed that the first exhaust days after LADG was 0.57 d shorter than that of CODG ($p < 0.05$) and the difference was statistically significant, as shown in fig. 5.

Meta-analysis of the number of days after the first meal:

A total of 10 studies comparing LADG and CODG's first eating days after surgery were included in this meta-analysis, with a sample size of 699 cases. Among them, 2 RCTs and 5 RNTs considered that the first feeding days after LADG were shorter than CODG and the difference was statistically significant; the remaining 2 RCTs and 1 RNT considered that the first feeding days after LADG and CODG were similar and there was no difference. Statistical significance; meta-analysis results showed that the first feeding days after LADG was 0.88 d shorter than CODG ($p < 0.05$) and the difference was statistically significant, as shown in fig. 6.

Meta-analysis of postoperative hospital stay:

A total of 13 studies compared the length of hospital stay after LADG and CODG were included in this meta-analysis sample size of 1206 cases. Among them, 2 RCTs and 7 RNTs considered that the postoperative hospital stay of LADG was less than that of CODG and the difference was statistically significant; the remaining 2 RCTs and 2 RNTs considered that the postoperative hospital stays of LADG and CODG were similar and there was no statistically significant difference; Meta-analysis results showed that the postoperative hospital stay of LADG was 4.76 d shorter than that of CODG ($p < 0.05$) and the difference was statistically significant, as shown in fig. 7.

Meta-analysis of the incidence of postoperative complications:

A total of 12 studies compared the incidence of complications after LADG and CODG were included in this meta-analysis, with a sample size of 1113 cases. The results of the meta-analysis showed that the postoperative complication rates of LADG and CODG were 7.95 % and 16.86 % respectively and the difference was statistically significant ($p < 0.05$), as shown in fig. 8.

Meta-analysis of postoperative mortality:

A total of 6 studies compared the postoperative mortality of LADG and CODG were included in this meta-analysis, with a sample size of 599 cases (including 3 studies due to the postoperative mortality of the LADG group and the CODG group all are 0, so they are excluded from this meta-analysis). The results of the meta-analysis showed that the postoperative mortality of LADG and CODG were 2.91 % and 1.72 % respectively and the difference was not statistically significant ($p = 0.74$), as shown in fig. 9.

DISCUSSIONS

Although laparoscopic radical surgery for early gastric cancer has become increasingly mature and has achieved good results, it has been listed as one of the standard treatment options for stage I gastric cancer by the 2002 Japanese Gastric Cancer Treatment Protocol^[1]. However, many studies believe that laparoscopic surgery is in terms of operating time. There is no obvious advantage. In a prospective comparative analysis of 24 cases of LADG and 23 cases of CODG, Yoshida *et al.* concluded that the operation time of the LADG group was longer than that of the CODG group and the difference was statistically significant^[6]. The retrospective studies of many scholars also believe that the operation time of the LADG group is longer than that of CODG. Yao *et al.* conducted a prospective analysis of 47 cases of LADG and concluded that although LADG has reached a certain level of technology in the treatment of early distal gastric cancer, it is still a time-consuming surgical procedure. On the one hand, because laparoscopic radical gastric cancer surgery requires multi-directional and multi-level anatomical separation of the perigastric space and extensive removal of the perigastric lymph nodes, most of the lymph nodes are located around important large blood vessels, making the operation difficult significant increase and prolong the operation time. On the other hand, because most surgeons are still in the "learning curve" of laparoscopic surgery, the "learning curve" is also one of the important factors affecting the operation time^[17]. The results of this study also showed that the operation time of the LADG group was longer than that of the CODG group. However, with the widespread development of laparoscopic early gastric cancer surgery, the surgeon's familiarity with the level of laparoscopic anatomy, the improvement of surgical skills, the accumulation of experience and the improvement of surgical instruments, the operation time will be shortened. We compare the operation time of laparoscopic early gastric cancer surgery from the same center at different times. It can be seen that the operation time in the latter phase of the study is significantly shorter than that in the previous phase. Hyung *et al.* analyzed the operation time of LADG for early distal gastric cancer in 2005 and 2008 respectively^[18] and the results showed that the operation time of LADG in 2005 was 319 min and in 2008 it was shortened to 285.8 min. Li *et al.* showed in the study on the "learning curve" that the operation time of each group of LADG gradually shortened with the increase of the number of cases, the operation time of 1-20 cases group was 351.2 min and the operation time of 41-60 cases group was

shortened to 280.8 min, the 81-100 cases group was 221.6 min^[19]. Therefore, although the operation time of laparoscopic early distal gastric cancer surgery is longer than that of traditional open surgery, with the continuous improvement of laparoscopic surgeons and the smooth passage of the "learning curve", the operation time will gradually shorten.

Laparoscopic surgery has changed the traditional operation method. It uses TV images to clearly magnify the real object several times, the operation field is clear, the blood vessel treatment is fine and the blindness of the operation is greatly reduced; coupled with the application of advanced hemostatic instruments such as ultrasonic knife, significantly reduces the amount of bleeding. In addition, the lighting used can reach the surgical site deeply, the surgeon's hands do not need to enter the patient's abdominal cavity and there is no need to separate tissues extensively, which greatly reduces the damage to the abdominal organs and interference with their functions, so that the patient's postoperative pain is reduced and recovered. The time is shortened, showing its minimally invasive advantages. In 1997, Goh *et al.* reported the results of a survey of 16 surgeons in 12 countries^[20]. Among them, 10 surgeons believed that LADG was superior to CODG because patients treated with laparoscopic surgery had a faster postoperative recovery, less pain and beautiful appearance. Kim *et al.* conducted a randomized controlled analysis of 164 cases of early-stage distal gastric cancer^[7]. The results showed that LADG compared with CODG reduced intraoperative blood loss by 155.6 ml, shortened the first postoperative gastric days by 0.2 d and shortened the first postoperative feeding 0.4 d, the length of hospital stay was shortened by 1.4 d and the difference between the two was statistically significant. The results of the meta-analysis of this study also confirmed that LADG has advantages over CODG in terms of surgical trauma, postoperative gastrointestinal function recovery and hospital stay.

Laparoscopic surgery not only has the advantages of minimally invasive surgery, many scholars believe that its postoperative complications rate is also significantly lower than traditional open surgery. Lee *et al.* retrospectively analyzed 106 cases of LADG and 105 cases of CODG^[18]. The results showed that the postoperative complication rate was 4.7 % in the LADG group and 13.3 % in the CODG group and the difference was statistically significant. Lin *et al.*^[21] conducted a retrospective comparative analysis of 87 cases of LADG and 101 cases of CODG and showed

that the incidence of postoperative complications in the LADG group was higher than that of Kitano *et al.* randomly compared the incidence of complications in 14 cases of LADG and 14 cases of CODG and found that, the incidence of complications in the two groups was similar. Chen *et al.*^[10] conducted a retrospective comparative analysis of 211 patients with early-stage distal gastric cancer and showed that the mortality of the LADG group and the CODG group were similar and the difference was not statistically significant. The results of the meta-analysis of this study showed that the incidence of postoperative complications in the LADG group was significantly lower than that in the CODG group and the mortality rate of the two groups was similar^[22].

From the results of the meta-analysis of this study, the short-term efficacy of LADG in the treatment of gastric cancer is significantly better than that of CODG, but it still needs to be further proved by a large-sample, multi-center, prospective randomized controlled study.
